

Export intensity and firm profitability: a synthetic example

M-AIDA demo (synthetic document, 2026)

Abstract

This document is not a study and reports no real data. It was written so that visitors can watch M-AIDA go from a PDF to a locked record without signing in. Every number in it is invented for the demonstration.

1. Data

The synthetic sample contains 240 manufacturing firms observed between 2016 and 2019. Export intensity is measured as exports divided by total sales; profitability is the return on assets.

2. Results

Table 2 reports the means, standard deviations and zero-order correlations. Export intensity is positively correlated with return on assets ($r = 0.18$, $p = 0.005$, $N = 240$).

Table 2. Descriptive statistics and correlations (synthetic, $N = 240$)

Variable	Mean	SD	1	2
1. Return on assets	0.061	0.042		
2. Export intensity	0.274	0.211	0.18	
3. Firm size (log employees)	4.12	1.08	0.11	0.24

In a regression with six control variables, the coefficient on export intensity is 0.15 ($t = 2.31$, $p = 0.022$).

3. What the demo shows

M-AIDA proposes the correlation and the sample size together with the sentences it read them from. A person compares both with the text, codes the moderators, approves and locks the record. Only locked records enter the forest plot and the exports.
